

1. Project Link: <https://microbit.org/projects/make-it-code-it/ai-light-switch/>
2. We chose this project because it was simple and could be done in the given time period.

To Do		
✓	Date	
☒	3/23	Find a micro:bit machine learning project to do
☐	3/24	get required materials for the project (AI Light Switch)
☐	3/24	Record the data for the micro:bit
☐	3/25	Test the code
☐	3/25	Test the AI Light Switch
☐	3/26	Finish the google doc for the assignment

3/23 - Chose the project

3/24 - Got the required materials for the project and started recording data

3/25 - Finished recording data and testing the code and the light switch

3/26 - Finished answering all the questions for the google doc

5. We need two microbits, a little bit of tape, and rubber bands to create a watch.

6. It went well but there was a problem when we were collecting data. The only problem was that the microbit kept disconnecting when we were collecting the data. Successes were that the AI light switch worked as expected and the AI could tell the difference between waving and clapping. What I didn't know at the start of this project was that you could teach an AI to tell the difference between different motions.

7. The AI in our program was responding to the microbit movements by either turning the LEDs on or off on the other microbit with clapping, turning it on and waving, turning it off or doing nothing if the microbit was still.

8. This program can be used ethically to help disabled people control the lights without using a light switch. The program can be used unethically by tracking people's movements throughout the day. AI is problematic because it can be biased and can invade privacy.

9. A safeguard for our program would be for it to stop tracking movements after the light turns off or on.

10.

Microbit off

Microbit on

Waving

clapping and microbit turning on
